

Sleeping card

**A playful interactive card that reacts
to human gestures**

Sleeping Card

Project Pitch

Sleeping Card is an interactive installation where a magical playing card comes to life through human gestures.

The project invites the player to wake, comfort, and energize a sleepy card using simple hand movements captured by a camera.

By knocking gently, framing with their hands, or moving them quickly, the user triggers different reactions the card wakes up, panics, shrinks, smiles, and finally shines.

Combining motion detection with animation and sound design, Sleeping Card transforms the screen into a living space of emotions.

The experience blends technology and empathy, showing how delicate gestures can awaken digital characters.

Through playful, intuitive interactions, the user becomes part of a poetic story where care and curiosity guide the outcome.

The Interface - Key visuals

User Journey

The player's gestures guide the Sleeping Card from rest to joy, turning simple motions into playful reactions.

The visitor follows the card through a simple three-step story. First, they wake her up by knocking, discovering that playing cards can “sleep” and react emotionally. Then, they help her regain her normal size by framing her with their hands, learning that cards have strict proportions that keep a deck balanced. Finally, they make her shine using a fast wave gesture, revealing the special coatings that make real cards glossy and durable. Each gesture advances the narrative and brings the Sleeping Card closer to being ready for the party.

Field observations

This project was inspired by how people naturally use movement to communicate.

During small preliminary tests, I showed a few simple on-screen elements to classmates: a sleeping face, a bouncing shape, and a tiny card icon. When interacting with them, people naturally used expressive gestures: some knocked on the screen to “wake” the sleeping icon, others waved or tried to frame the moving shapes with their hands.

These reactions revealed how intuitive hand movements are when people try to communicate with digital objects.

This insight became the foundation for Sleeping Card and its gesture-based interactions.

User Tests

Short tests were made to see how people react to the Sleeping Card and its gestures. The goal was to check if the actions felt natural and easy to understand.

During the first sessions, users quickly understood that a tap could wake the card.

Some tried different gestures waving, clapping, or forming shapes which helped refine the interaction system.

Most users smiled or laughed when the card reacted, confirming the emotional connection worked well.

Scenography

Make a visual, sketch or high quality photo showing all elements of your installation in perspective.

Spatial diagram

This top view illustrates the setup of the Sleeping Card installation.

The layout shows the TV screen positioned against the wall with a webcam mounted above it and a laptop placed behind on a small table.

Technical diagram

A laptop runs the interactive program, processing hand gestures detected by a webcam positioned above the TV screen.

The webcam connects to the laptop via USB, while the laptop sends the visual output to the TV through an HDMI connection.

This simple configuration allows the system to capture, interpret, and display gestures in real time.
